# Informed Search Lecture 5

How can we exploit problem-specific knowledge to find solutions more efficiently?

Where does this knowledge come from and under what conditions is it useful?

# Agenda

- Review: Uninformed Search
- Informing Search via Heuristics
- Best-First Search: Greedy, A\*
  Properties: Admissibility, Consistency
- Heuristic Origins

# Search Problem Formalism

Defined via the following components:

- The initial state the agent starts in
- A successor/transition function
  - $S(x) = \{action+cost->state\}$
- A goal test, which determines whether a given state is a goal state
- A path cost that assigns a numeric cost to each path

A **solution** is a sequence of actions leading from initial state to a goal state. (**Optimal** = lowest path cost.)

Together the initial state and successor function implicitly define the **state space**, the set of all reachable states

COMP3770 – Artificial Intelligence

Spring 2016 | Derbinsky

# State Space Graph

- State space graph: A mathematical representation of a search problem
  - Nodes are (abstracted) world configurations
  - Arcs represent successors (action results)
  - The goal test is a set of goal node(s)
- In a search graph, each state ( occurs only once!
- We can rarely build this full graph in memory (it's too big), but it's a useful idea

Spring 2016 | Derbinsky

# Search Tree

- A "what if" tree of plans and their outcomes
- The start state is the root node
- Children correspond to successors
- Nodes show states, but correspond to PLANS that achieve those states
- For most problems, we can never actually build the whole tree

Spring 2016 | Derbinsky

# Searching for Solutions

Basic idea: incrementally build a search tree until a goal state is found

- Root = initial state
- Expand via transition function to create new nodes
- Nodes that haven't been expanded are leaf nodes and form the frontier (open list)
- Different **search strategies** (next lecture) choose next node to expand (as few as possible!)
- Use a **closed list** to prevent expanding the same state more than once

# General Algorithm

function GRAPH-SEARCH( problem, fringe) returns a solution, or failure closed ← an empty set fringe ← INSERT(MAKE-NODE(INITIAL-STATE[problem]), fringe) loop do if fringe is empty then return failure node REMOVE-FRONT(fringe) if GOAL-TEST(problem, STATE[node]) then return node if STATE[node] is not in closed then

> add STATE[node] to closed fringe ← INSERTALL(EXPAND(node, problem), fringe)

### $\mathbf{end}$

**Informed Search** 

Queue (FIFO) Stack (LIFO) Priority Queue • f(n)

# Evaluating a Search Strategy

### Solution

- Completeness: does it always find a solution if one exists?
- **Optimality**: does it always find a least-cost solution?

## Efficiency

- Time Complexity: number of nodes generated/expanded
- Space Complexity: maximum number of nodes in memory

# Uninformed Search

Search given only the problem definition

	DFS	BFS	UCS
Fringe	LIFO (stack)	FIFO (queue)	PQ (path cost)
Complete		Х	X
Optimal			Х
Time	$\mathcal{O}(b^m)$	$\mathcal{O}(b^s)$	$\mathcal{O}(b^{\mathcal{C}^*/\varepsilon})$
Space	$\mathcal{O}(bm)$	$\mathcal{O}(b^s)$	$\mathcal{O}(b^{C^*/\varepsilon})$
		•. •.• .•	

Assumptions: potentially infinite depth, arbitrary positive action costs

Spring 2016 | Derbinsky

# Let's Inform the Search

# Search Heuristic

A[n] heuristic is...

- a function, h(n), that estimates how close the input state is from a goal state
- designed for a particular problem

Examples: distance (Manhattan, Euclidean)

**Informed Search** 

# Example Search Heuristic

# The Pancake Problem

### **BOUNDS FOR SORTING BY PREFIX REVERSAL**

William H. GATES Microsoft, Albuquerque, New Mexico

Christos H. PAPADIMITRIOU\*<sup>†</sup> Department of Electrical Engineering, University of California, Berkeley, CA 94720, U.S.A.

Received 18 January 1978 Revised 28 August 1978

For a permutation  $\sigma$  of the integers from 1 to n, let  $f(\sigma)$  be the smallest number of prefix reversals that will transform  $\sigma$  to the identity permutation, and let f(n) be the largest such  $f(\sigma)$  for all  $\sigma$  in (the symmetric group)  $S_n$ . We show that  $f(n) \leq (5n+5)/3$ , and that  $f(n) \geq 17n/16$  for n a multiple of 16. If, furthermore, each integer is required to participate in an even number of reversed prefixes, the corresponding function g(n) is shown to obey  $3n/2 - 1 \leq g(n) \leq 2n+3$ .

#### 1. Introduction

We introduce our problem by the following quotation from [1]

The chef in our place is sloppy, and when he prepares a stack of pancakes they come out all different sizes. Therefore, when I deliver them to a customer, on the way to the table I rearrange them (so that the smallest winds up on top, and so on, down to the largest at the bottom) by grabbing several from the top and flipping them over, repeating this (varying the number I flip) as many times as necessary. If there are *n* pancakes, what is the maximum number of flips (as a function f(n) of *n*) that I will ever have to use to rearrange them?

COMP3770 – Artificial Intelligence

Spring 2016 | Derbinsky

## Pancake Problem

## Cost: number of pancakes flipped

# [Partial] State Space Graph

# Example Graph Search

Spring 2016 De

### Derbinsky

Heuristic: number of the largest pancake out of place

# **Best-First Search**

- In Graph Search, apply f(n), an evaluation function, for each node
  - Estimates "desirability"
- Typical decomposition of f(n)
  - -g(n): cost to reach n from initial state
  - -h(n): heuristic function
    - Estimate of distance to goal

## **Special cases**

- Uniform-Cost Search (**UCS**): f(n) = g(n)
- **Greedy** Best-First Search: f(n) = h(n)
- A\* Search: f(n) = g(n) + h(n)

# **Greedy Best-First Search**

Spring 2016 | Derbinsky

# **Target Problem**

# **Greedy Best-First Search**

# **Greedy Analysis**

- Best case
  - Take you directly to the nearest goal
- Common case - Takes you [less-thanoptimally] to a goal
- Worst case
  - Like badly guided DFS

February 16, 2016

# Greedy Evaluation

### <u>Time</u>

\$\mathcal{O}(b^m)\$
 Can improve dramatically with a good heuristic

m tiers

### <u>Space</u>

•  $\mathcal{O}(b^m)$ 

### <u>Complete</u>

• Only if finite

### <u>Optimal</u>

• No

Maze-Greedy

PacMan-Greedy

A\* Search

# Combining UCS and Greedy

- UCS: orders by path, or backward, cost, g(n)
- Greedy: orders by goal proximity, or forward cost, h(n)
- A\*: orders by the sum: f(n) = g(n) + h(n)

![](_page_24_Picture_8.jpeg)

## A\* Search

![](_page_25_Figure_3.jpeg)

![](_page_25_Picture_4.jpeg)

# UCS vs. A\*

 Uniform-cost expands equally in all "directions"

 A\* expands mainly toward the goal, but does hedge its bets to ensure optimality

![](_page_26_Picture_6.jpeg)

![](_page_26_Picture_7.jpeg)

![](_page_26_Picture_8.jpeg)

![](_page_26_Picture_9.jpeg)

February 16, 2016

Wentworth Institute of Technology

![](_page_27_Figure_3.jpeg)

![](_page_27_Figure_4.jpeg)

# To ensure optimality, we need certain *properties* to hold on the heuristic function

![](_page_27_Picture_6.jpeg)

# Property #1: Admissibility

- An admissible heuristic never overestimates cost to the goal
- Consequence: f(n) never overestimates
  -f(n) = g(n) + h(n)
  -g(n) reflects actual path cost

• Example: straight-line distance (SLD)

![](_page_28_Picture_7.jpeg)

Wentworth Institute of Technology

## **Issue Revisited**

![](_page_29_Figure_4.jpeg)

• Is h(n) admissible?

![](_page_29_Picture_6.jpeg)

COMP3770 – Artificial Intelligence

Spring 2016 Derbinsky

# Idea: Admissibility

![](_page_30_Picture_4.jpeg)

![](_page_30_Picture_5.jpeg)

Inadmissible (pessimistic) heuristics break optimality by trapping good plans on the fringe Admissible (optimistic) heuristics slow down bad plans but never outweigh true costs

![](_page_30_Picture_8.jpeg)

Informed Search

# Checkup

For an admissible heuristic, what must the value of h(g) be, if g is a goal?

In general...

## $0 \le h(n) \le h^*(n)$

## where $h^*(n)$ is <u>true</u> cost to a nearest goal

![](_page_31_Picture_8.jpeg)

# Property #2: Consistency/Monotonicity

A[n] heuristic is **consistent** iff...

- for every node *n*,
- and every successor *n*' of *n* generated via action *a*,
- the estimated cost of reaching the goal from n is no greater than the step cost of getting to n plus the estimated cost of reaching the goal from n'

![](_page_32_Figure_8.jpeg)

 $h(n) \le c(n, a, n') + h(n')$ 

![](_page_32_Picture_10.jpeg)

# Implication of Consistency

## If a[n] heuristic is consistent, f(n) never decreases along a path

Proof... 
$$f(n')$$
  
=  $g(n') + h(n')$   
=  $g(n) + c(n, a, n') + h(n')$   
 $\ge g(n) + h(n) = f(n)$ 

![](_page_33_Figure_6.jpeg)

![](_page_33_Picture_7.jpeg)

## Checkup

State Space Graph

![](_page_34_Figure_5.jpeg)

![](_page_34_Figure_6.jpeg)

**Search Tree** 

- Admissible?
- Consistent?

![](_page_34_Picture_9.jpeg)

# **Consistency of Heuristics**

![](_page_35_Figure_4.jpeg)

## <u>Admissibility</u>

• Heuristic  $\leq$  actual cost  $h(A) \leq c(A, G)$ 

## **Consistency**

• Heuristic  $\leq$  actual arc  $h(A) - h(C) \leq c(A, C)$ 

![](_page_35_Picture_9.jpeg)

# Optimality of A\* Graph Search

![](_page_36_Picture_4.jpeg)

- If h(n) is consistent, A\* Graph Search is **optimal**
- All consistent heuristics are admissible
  - Most admissible heuristics are also consistent
  - Most of your time applying A<sup>\*</sup> is finding the right h(n)

![](_page_36_Picture_9.jpeg)

Spring 2016 | Derbinsky

# **Proof Ideas**

Let's assume positive action costs

- 1. A\* expands nodes in increasing total *f* value (*f-contours*)
- 2. The optimal goal(s) have the lowest *f* value, so it must get expanded first

![](_page_37_Figure_7.jpeg)

![](_page_37_Picture_8.jpeg)

COMP3770 – Artificial Intelligence

Spring 2016 | Derbinsky

# A\* Optimality Proof

- 1. Assume some n on path to  $G^*$  isn't in the fringe when we need it, b/c some worse n' for the same state popped and expanded first
- 2. Let p be the ancestor of n that was on the queue when n' was popped

![](_page_38_Picture_6.jpeg)

- 3. f(p) < f(n): consistency
- 4. f(n) < f(n'): n' suboptimality
- 5.  $\therefore p$  would have been expanded before n': **contradiction!**

![](_page_38_Picture_10.jpeg)

)16 Derbinsky

# A\* Evaluation

### <u>Time</u>

 Strongly related to the problem and heuristic; exponential w.r.t. error/solution length

### <u>Space</u>

 Whole tree (see book for ID-A, RBFS, SMA\*)

### <u>Complete</u>

Yes, assuming positive action costs

### <u>Optimal</u>

 Yes, assuming consistent heuristic

![](_page_39_Picture_12.jpeg)

- A\* expands all nodes with  $f(n) < C^*$
- A\* expands some nodes with  $f(n) = C^*$
- A\* expands <u>**no</u>** nodes with  $f(n) > C^*$ </u>

![](_page_39_Picture_16.jpeg)

# A\* Applications

- Video games
- Pathing / routing problems
- Resource planning
  problems
- Robot motion planning
- Language analysis
- Machine translation
- Speech recognition

![](_page_40_Picture_11.jpeg)

![](_page_40_Picture_12.jpeg)

# **Creating Heuristics**

![](_page_41_Picture_4.jpeg)

![](_page_41_Picture_5.jpeg)

# **Heuristics Tradeoff**

- There is a trade-off between quality of the goal estimate and the expended work per node to generate the estimate
- As heuristics get closer to the true cost, you will expand fewer nodes but usually do more work per node to compute the heuristic itself
  - As an extreme, consider using true cost
- Often, heuristics are solutions to **relaxed** (i.e. easier) • problems, where new actions are available
  - Key point: the optimal solution cost of the relaxed problem must not over-estimate the optimal solution cost of the real problem

![](_page_42_Picture_9.jpeg)

![](_page_42_Picture_10.jpeg)

# Heuristic Dominance

- Assume consistent heuristics:  $h_1$ ,  $h_2$ , ...
- $\forall n h_1(n) \ge h_2(n) \equiv h_1$  dominates  $h_2$ -  $h_1$  is better for search
- If no heuristic dominates in all states, consider h<sub>max</sub>(n) = max{h<sub>1</sub>(n), h<sub>2</sub>(n), ...}
   - h<sub>max</sub> is consistent
  - $-h_{max}$  is a dominant heuristic over the set

![](_page_46_Picture_8.jpeg)

# Heuristic Hierarchy

- Bottom is the trivial, or zero, heuristic
   ∀n h(n) = 0
- Top is the exact solution

![](_page_47_Picture_6.jpeg)

![](_page_47_Picture_7.jpeg)

# Summary (1)

- Heuristics are problemspecific functions that estimate how close the input state is from a goal state
- Good heuristics can dramatically reduce search cost

![](_page_48_Picture_4.jpeg)

![](_page_48_Picture_5.jpeg)

Derbinsky

COMP3770 – Artificial Intelligence

Spring 2016 | Derbinsky

# Summary (2)

- Best-first search uses an evaluation function
  - UCS: g(n)
  - Greedy: h(n)
  - $A^*: g(n) + h(n)$
- A\* is complete and optimal given a consistent heuristic
- Consistent heuristics can be derived from solutions to relaxed problems
  - Exploiting dominance can lead to even better heuristics
